## INTRODUCTION

Among health care professionals, there is a general consensus that certain health conditions and behavior patterns have a strong correlation with disease, injury and death. Examples include cigarette smoking, physical inactivity, overweight/obesity, and alcohol consumption. The Behavioral Risk Factor Surveillance System (BRFSS) is a telephone surveillance system designed to estimate the prevalence of these along with other health risk factors in every state and some territories in the United States (U.S.). The results provide a tool for evaluating health trends, assessing the risk of chronic diseases, and measuring the effectiveness of policies, programs, intervention strategies and awareness campaigns.

The BRFSS is a cooperative agreement between the Centers for Disease Control and Prevention (CDC) and the Mississippi State Department of Health (MSDH). The first survey was conducted in 1984 when the data were collected at one given point in time. The survey was repeated in 1988 using the same methodology. Beginning from 1990, states have completed an annual survey with the data being collected monthly.

The BRFSS survey contains a set of core questions provided by the CDC to gather comprehensive standard information nationwide. The questions are related to health status, access to health care, health awareness, lifestyles, and preventive health. The CDC provides states with opportunities to also include questions addressing specific risk factors that are of particular concern and/or interest to that state. In 2018, Mississippi included ten BRFSS optional question modules.

## A. 2018 Sampling Design

The Mississippi BRFSS is a randomly sampled telephone survey that utilizes a disproportionate stratified sample (DSS) design with random digit dialing and a Computer Assisted Telephone Interviewing (CATI) system. A sample size of 5,843 interviews were conducted in 2018 over a 12month period. This produced a 95 percent confidence interval for prevalence estimates for Mississippi's adult population. Prevalence estimates by individual demographic variables, comprising smaller sample sizes, do not achieve the same level of accuracy as the total sample.

Until the 2011 survey, the BRFSS had relied exclusively on interviews of households with only landline phones; however, the number of households having only cell phones have increased. The CDC reports that as of December 2015, almost half ( 47 percent) of households in the U.S. have only cell phones.

For landline surveys, interviewers contact the residences during weekdays between 9:00 a.m. and 9:00 p.m. and Saturdays between 10:00 a.m. and 4:30 p.m. After a residence has been contacted, one adult (18 years of age or older) is randomly selected to be interviewed from all adults residing in the household. The majority of interviews are collected over a two-week period each month of the survey year.

For cell phone surveys, the same protocol is followed except that the interviewer establishes that the person answering the phone is at least 18 years of age. This method provides the interviewer with a verbal agreeance that it is safe for the respondent to be interviewed and that the person uses the cell phone for at least 90 percent of their telephone service. Also, for cell phone surveys no random adult is selected.

## B. Questionnaire

The questionnaire, designed through cooperative agreements with the CDC, is divided into three sections. The first section contains questions on health conditions and behavior; the second section contains demographic information; and the third contains optional modules covering topics of interest to the state.

## C. Data Analysis

Since 2011 the BRFSS has utilized a different weighting method called iterative proportional fitting, also known as "raking." The procedure, while not new, has been made feasible through the development of ultra-fast computer processors. In addition to the standard age, gender, race and ethnicity variables, the use of raking allows for consideration of demographic variables such as education level, marital status, renter or owner status, and phone source. By including these additional variables into the weighting process, the survey will more accurately reflect Mississippi's adult population. The data collected by the MSDH are edited and weighted by the CDC. In addition, CDC sends each state their analyses which includes weights, confidence intervals, percentages, and N counts known as a Calculated Variables Data Report. Weighted counts were based on the 2018 Nielsen and ACS Adult Population Report for Mississippi population estimates to accurately reflect the state's demographics. According to the report, Mississippi's population count is 2,279,079 for 2018.

## D. Limitations of Data

All data collection systems are subject to error, and records may be incomplete and/or contain inaccurate information. All data collected via the BRFSS program are self-reported. It is not always possible to measure the magnitude of these errors or their impact on the data. The user must be the final arbiter in evaluating the accuracy of the data. In addition, respondents who did not answer and/or refused to respond are not included in the percentages listed in this report.

## E. Sample Size

In the 2018 BRFSS, 5,843 people were sampled: 28.67 percent responded to the survey using a landline and 71.33 percent responded using a cell phone. The reader should note that sample sizes by question and response category may vary because of non-response and skip patterns within the survey instrument. Overall estimates generally have relatively small sampling errors and estimates for certain population subgroups may be based on small numbers and have relatively large sampling errors. Interpreting estimates that are based on small numbers can mislead the reader into believing that a given finding is more precise than it really is. When the number of events is small and the probability of such an event is small, considerable caution should be observed in interpreting the estimates or differences among groups. The BRFSS recommends not interpreting percentages where the denominator is based upon fewer than 50 non-weighted respondents.

NOTE: Only select Mississippi BRFSS health indicators are included in this report. For other data analyses not included in this report, please contact the MSDH BRFSS Program Manager at Vernesia.Wilson@msdh.ms.gov or by phone at 601-576-8165.

## MS BRFSS DATA BRIEFS

## Core Questions

## Health Status

Health status is an indicator that attempts to determine how adults look at their personal health and how well they function physically, psychologically and socially while engaged in normal, daily activities. The questions related to health status are important because they may

Health Status Question:
Would you say that in general your health is excellent, very good, good, fair, or poor? indicate dysfunction and disability not measured in standard morbidity and mortality data.

With respect to race and gender, black females reported the highest percentage of health that was fair or poor with a rate of 28.4 percent (Figure 1). Black respondents overall reported their health as worse than whites. Overall, Black respondents reported fair or poor health at a rate of 27 percent compared to 21.9 percent for whites. Males in the 18 to 24 age group reported the lowest rate of their health as fair or poor at a rate of only 4.1 percent while those ages 65 and older in both male and female groups at a rate of 36.7 and 36.1 percent respectively (Figure 2).

In regard to fair or poor health by education, those with higher education levels reported a lower rate at 10.5 percent compared to those with less than a high school diploma (Figure 3). Similarly, respondents with higher annual household incomes reported lower rates of fair or poor health (Figure 4).

Figure 4. Health Status By Annual Household Income and Gender

$\square$ Female $\square$ Male

## Health Care Coverage

The healthcare coverage question is designed to estimate the number of people in the state who cannot obtain the health care they need because they are not covered by a health care plan or other

Health Care Coverage Question:
Do you have any kind of health care coverage, including health
insurance, prepaid plans such as HMOs, or government plans such as Medicare, or Indian Health Service?
health insurance. People at risk of adverse health conditions are those without any coverage and/or unable to afford coverage.

Overall, other races (non-Hispanic) had the highest rate of non-coverage at 37.3 percent, followed by blacks at 22.1 percent (Figure 5).

In 2018, 20.3 percent of respondents indicated they had no health care coverage and/or plan compared to 17 percent in 2017. According to the results, black males continue to have the highest rate of non-coverage at 24.1 percent compared to 23.9 in 2017.

Interestingly, females ages 18-24 had the highest rate of non-coverage at 30 percent (Figure 6) compared to males in the same age group.

Males with less than a high school diploma had the highest rate of non-coverage at 35.6 percent (Figure 7); while adults with annual household incomes of $\$ 75,000$ or more had the lowest rates of non-coverage (Figure 8).

## EXERCISE AND PHYSICAL ACTIVITY

Regular physical activity helps to maintain the functional independence of older adults and enhances the quality of life for people of all ages. The role of physical activity in preventing coronary heart disease (CHD) is of particular importance, given that CHD is the leading cause of death among all

Exercise and Physical Activity Question: During the past month, other than your regular job, did you participate in any physical activities or exercises such as running, calisthenics, golf, gardening, or walking for exercise?
diseases and conditions. Physically inactive people are almost twice as likely to develop CHD as persons who engage in regular physical activity (Roth \& Townsend, 2003). The risk posed by physical inactivity is almost as high as several well-known CHD risk factors such as cigarette smoking, hypertension, and high blood cholesterol.

Regular physical activity is important for people who have joint or bone problems. It has been shown to improve muscle function, cardiovascular function, and physical performance. People with osteoporosis may respond positively to regular physical activity, particularly weight- bearing activities such as walking and especially when combined with appropriate drug therapy and calcium intake.

In Mississippi, 2018 data indicate that 32 percent of the population reported not participating in any physical activity outside of work in the past 30 days (Figure 9). In both males and females, the highest inactivity rate was among those aged 65 and older (Figure 10). As with several other indicators those respondents with less than a high school diploma reported the highest rate of physical inactivity at 47 percent (Figure 11) as true with respondents who reported lower annual household income levels (Figure 12).

## Coronary Heart Disease / Stroke

Cardiovascular disease (CVD) includes coronary heart disease, stroke, complications of hypertension, and diseases of the arterial blood vessels. In addition to causing almost a third of all deaths in Mississippi in 2017, CVD is one of the major causes of premature,

## Coronary Heart Disease/Stroke Question:

Has a doctor, nurse, or other health professional ever told you that you had any of the following: Angina or coronary heart disease? A stroke?
permanent disability among working adults.

In 2017, Mississippi reported 7,936 deaths from heart disease (number one cause of death in the state) and 1,717 from cerebrovascular disease (stroke). The two combined accounted for almost thirty percent of all the deaths reported that year.

The 2018 BRFSS data results indicate that 8.5 percent of respondents were told by a healthcare professional that they had coronary heart disease (CHD) or stroke. Of this percentage, 9.3 percent are white, 7.2 percent are black, and 15.1 percent are of another race (Figure 13). Similar to other chronic conditions, as people age, so does the prevalence of coronary heart disease or stroke, as indicated in Figure 14. In each age group, males had the higher rates of being told they had coronary heart disease or stroke.

As indicated in Figure 15, as education levels increased, the rate of coronary heart disease or stroke decreased. This same statistic is true for annual household income levels (Figure 16) with the exception of the $\$ 35,000-\$ 49,999$ level for females and the $\$ 75,000$ or more income level for males. Both of these income groups slightly increased from the preceding income levels.

## ASTHMA AWARENESS

According to the U. S. Department of Health and Human Services (2020) Healthy People 2020 publication, asthma is a chronic inflammatory disorder of the airways characterized by episodes of reversible breathing problems due to airway narrowing and obstruction. These episodes can range in severity from mild to life threatening. Symptoms of asthma include wheezing, coughing, chest tightness, and shortness of breath. Sometimes, breathing may be quite labored whereby an asthma attack becomes life-threatening.

In Mississippi, the 2018 BRFSS survey revealed that 15.2 percent of respondents indicated that a health professional told them they had asthma. Black females reported a higher rate of asthma, 16.7 percent, compared to other groups (Figure 17).

Both male and female respondents ages 18-24 had the highest rates of being told they ever had asthma by a health professional (Figure 18). Overall, respondents who are college graduates reported lower rates of being told they ever had asthma (Figure 19).

Figure 20 indicates that both males and females with annual household incomes of \$75,000 or more had lower rates of being told they had ever had asthma.

## CURRENTLY HAVE ASTHMA

Most of the problems caused by asthma could potentially be avoided if persons with asthma and their health care providers managed the disease according to established guidelines. Effective management

## Currently Have

 Asthma Question:Has a doctor, nurse, or other health
professional ever told you that you had asthma? If Yes, do you still have asthma? of asthma comprises four major components: (1) controlling exposure to factors that trigger asthma episodes, (2) managing asthma with medicine, (3) monitoring the disease by using objective measures of lung function, and (4) educating asthma patients to become partners in their own care. Such prevention efforts are essential to interrupt the progression from disease to functional limitation and disability and to improve the quality of life for persons with asthma.

The 2018 BRFSS indicates that 9.7 percent of respondents said that they currently [still] have asthma-among those who answered yes to ever being told by a health professional they ever had asthma. Figure 21 indicates that black females have the highest rate of asthma at 12.3 percent, compared to other groups. Overall females in each age group had higher rates of asthma compared to men (Figure 22); college graduates had the lowest rates compared to those who had less education (Figure 23). Similar to other health indicators, respondents with annual household income levels of $\$ 75,000$ or more had lower rates of asthma than those in lower income groups (Figure 24).

## ARTHRITIS

Arthritis has the potential to be quite debilitating to those suffering from this condition. According to the Healthy People 2020 (U.S. Department of Health and Human Services, 2020) publication, arthritis

Arthritis Question:
Has a doctor, nurse, or other health
professional ever told you that you have some form of
arthritis, rheumatoid arthritis, gout, lupus, or fibromyalgia?
affects one in five adults in the United States and continues to be the most common cause of disability and adds more than $\$ 128$ billion per year to the cost of health care. All of the human and economic costs are projected to increase over time as the population ages.

The significant public health impact of arthritis is reflected in a variety of measures. First, arthritis is one of the leading causes of disability, especially among working people. Arthritis substantially limits major activities such as regular work, housekeeping and school for nearly three percent of the U.S. population and almost twenty percent of those who are afflicted with the condition. Arthritis trails only heart disease as a cause of work disability. As a consequence, arthritis limits the independence of affected persons and disrupts the lives of family members and other care givers.

Overall, in Mississippi (2018), females had a higher rate of arthritis at 36.3 percent compared to males at 27.7 percent. As indicated in Figure 25, white females had the highest rate among all groups at 39.2 percent. As indicated in Figure 26, the proportion of adults having ever been told by a healthcare professional they have arthritis increases with age.

The 2018 BRFSS results also indicate that for both males and females, the rates of arthritis decrease as levels of education increase (Figure 27). Rates of arthritis are also lower for both males and females who have annual household incomes of $\$ 50,000$ or more (Figure 28).

## Mental Health Status

In both public and private medicine, the concept of health-related quality of life refers to the physical and mental health perceived by a person or a group of persons. Health care professionals use health-

> Mental Health Question:
> Now thinking about your mental health, which includes stress, depression, and problems with emotions, for how many days during the past 30 days was your mental health not good? related quality of life to measure the effects of chronic illness in patients and to better understand how an illness interferes with the day-to-day life activities of an individual. Similarly, health professionals use healthrelated quality of life to measure the effects of numerous disorders, shortterm and long-term disabilities, and diseases in different populations. Tracking health-related quality of life in different populations can aid in identifying subgroups with poor physical or mental health and can help in developing policies or interventions to improve their health.

In Mississippi, the 2018 BRFSS indicated that 15.5 percent of respondents had fourteen or more (14+) days of poor mental health. White females had the higher rate of poor mental health at 17.6 percent compared to other groups (Figure 29). As indicated in Figure 30, poor mental health is lower among those who are aged 65 or older and those with a college degree (Figure 31). In addition, poor mental health is highest ( 30.4 percent) among males whose annual household incomes are less than $\$ 15,000$ compared to males and females in other annual income levels.

## OVERWEIGHT AND ObESITY/BODY MASS INDEX (BMI)

The proportion of overweight persons has increased substantially during the past twenty years. Even though some progress has been made, there are short falls for healthy physical activity and dietary-

## BMI Questions:

(1) About how much do you weigh without shoes? (2) About how tall are you without shoes? consumption levels, leaving more than a third of adults obese (CDC, n.d.). Overweight persons substantially increase their risk of illness from hypertension, high cholesterol, Type 2 diabetes, heart disease and stroke, gall bladder disease, cancer of the endometrium, breast, prostate and colon as well as arthritis. Overweight people may also suffer from social stigmatization, discrimination, and low self-esteem.

Weight may be controlled by dietary changes such as decreasing caloric intake and by increasing physical activity. According to 2018 BRFSS results, 73.3 [cumulative] percent of respondents reported themselves to be overweight ( $\mathrm{BMI} \geq 25$ ) or obese ( $\mathrm{BMI} \geq 30$ ). Mississippi's obesity rate for 2018 was 39.5 percent which is an increase from 37.3 percent in 2017.

In 2018, black females had the highest rate of obesity at 53.9 percent (Figure 33). Both females and males between the ages of 35-54 had the highest obesity rates (Figure 34 ) compared to other age groups. Overall, the obesity rate for those with a college degree is lower than other education groups at 35.9 percent (Figure 35). As indicated in Figure 36, the obesity rate is lower among females with annual household incomes of $\$ 75,000$ or more; however, the rate is higher among males with annual household incomes between $\$ 15,000-\$ 24,999$ and $\$ 75,000$ or more.

Breast and cervical cancer are conditions that highly impact women in Mississippi and across the U.S. each year. Over a lifetime, the probability of a woman getting breast cancer is currently around 1:8 (Susan G Komen, 2019).

Breast/Cervical
Cancer Screening Question:
(1) Have you ever had a mammogram?

Note: Analyses include women 40 and older

Breast and cervical screenings are important preventative measures that can be taken to lessen the mortality from these conditions. In 2017, there were a total of 490 deaths from [female] breast cancer in Mississippi. Of these deaths, 278 ( $56.7 \%$ ) were white women and 212 (43.3\%) were black.

The cancer objectives for Healthy People 2020 support monitoring trends in cancer incidence, mortality, and survival to better assess the progress made toward decreasing the burden of cancer in the United States. The objectives reflect the importance of promoting evidence-based screening for cervical, colorectal, and breast cancer by measuring the use of screening tests (Healthy People, 2020), such as mammograms.

According to the 2018 BRFSS data results, 65.3 percent of women who were 40 and older indicated that they had a mammogram. As indicated in Figure 37, more black women ( 71.7 percent) than white ( 62.9 percent) responded that they had ever had a mammogram. Women between the ages of 55-64 had the highest rate (71.1 percent) of mammogram screenings compared to the other three age groups (Figure 38). As with several other health indicators, women aged 40 and older who have a college degree had the highest rate ( 75.7 percent) of mammogram screenings (Figure 39), in addition to those with annual household incomes of $\$ 50,000$ annually or more (Figure 40).

## Breast and Cervical Cancer Screenings (Pap Tests)

Pap tests/screenings have been proven to be a prevention method for early detection of any abnormal cells in the cervix. These tests are used by physicians and produce results that are relied upon to reveal any abnormalities. According to the Mayo Clinic (2019), detecting cervical cancer early with a pap test gives females a greater chance at a cure.

Practicing healthy habits such as not smoking, condom usage, and receiving early screenings are some of the measures that lower women's risks of cervical cancer. In addition, practicing good sexual health is a strong measure to reduce the risk of the condition. Because the Human Papillomavirus (H.P.V.) is one of the known causes of cervical cancer and is transmitted through sexual contact, women can reduce their risk of cervical cancer by practicing good sexual health and also by receiving HPV vaccinations for further protection.

The 2018 Mississippi BRFSS results among women ages 21-65 revealed that 82.3 percent had a pap test in the past three years. As indicated in Figure 41, more black women ( 90.8 percent) than white ( 76.9 percent) received a pap test in the past three years. Women ages $25-34$ had the highest rate of pap screenings at 92.8 percent (Figure 42). Women under the age of 21 were excluded in the final counts.

Figure 43 indicates that women ages 21-65 with less than a high school diploma had the lowest rate of pap screenings at 67.6 percent. Subsequently, women with annual household incomes between less than $\$ 15,000$ and $\$ 34,999$ had lower rates of pap screenings compared to women in higher income levels (Figure 44).

## PROSTATE CANCER SCREENING

According to the American Cancer Society (2020), prostate cancer is the second leading cause of cancer death among men in the United States, behind only lung cancer. Screenings for prostate cancer,

Prostate Cancer Screening Question:
(1) Have you ever had a P.S.A. test?

Note: Analyses include men 40 years of age and older also known as the prostate-specific antigen or P.S.A. test, allows medical professionals to identify signs of prostate cancer in male patients. As with many preventative measures, these (or similar) screenings may detect abnormalities early which enhances the treatment and potentially increase survival rates.

In addition, males can assess their risk of prostate cancer by taking precautions, especially if he is African American and/or has a family history of the disease.

The 2018 BRFSS data indicate that 35.4 percent of men ages 40 and older responded that they ever had a P.S.A. test. Figure 45 indicates that 36.3 percent of white males responded ever having a P.S.A. test compared to 34.4 percent of black males. As the age of men increased, so did the rate of P.S.A. screenings (Figure 46). Figure 47 indicates that men 40 and older with less than a high school diploma had the lowest rate of P.S.A. screenings at 25.6 percent. Men with annual household incomes of $\$ 50,000$ or more had the highest rates of P.S.A. screenings (Figure 48) compared to those with less than $\$ 50,000$ annual household incomes.

In 2017, there were 627 deaths from colorectal cancer in Mississippi. Of this number 384 (61.2\%) were white, 236 ( $37.6 \%$ ) were black and 7 ( $1.1 \%$ ) were of other races. This particular type of cancer forms in the colon or rectum and it is estimated that 150,000 men and women in the U.S. have this condition.

Colorectal cancer is one of the most preventable cancers since it typically develops from polyps that can be detected and removed before they become cancerous. There are prevention strategies that people can use to lower the risk of colorectal cancer. These include, but are not limited to, receiving regular screening tests, exercising regularly, and eating a diet rich in fruits, vegetables, and whole grains. Also, men and women who receive colonoscopies allows their medical provider to check for any signs of colorectal cancer. These screenings are recommended in patients 50 and older unless they exhibit signs/symptoms of colorectal cancer before the age of 50 .

The 2018 BRFSS results revealed that 60.1 percent of adults age 50 and older received a colonoscopy within the past 10 years, which categorized them as "not at risk" for colorectal cancer. There were more females than males whom received a colonoscopy in the past 10 years (Figure 49). As indicated in Figure 50, as people aged (both male and female), the rates of screenings increased. Overall, as education levels increased and in those with annual household incomes of $\$ 75,000$ or more, so did the rates of colorectal screenings in both males and females (Figures 51 and 52). In addition, 62.6 percent of Mississippi adults ( 50 and over) met the United States Preventive Services Task Force (USPSTF, 2016) colorectal screening recommendation and/or were compliant in 2018.

## Cigarette/Tobacco Use

Tobacco use is the single leading preventable cause of death in Mississippi and the United States. Each year, about one-fifth of the deaths in Mississippi are from tobacco- related causes. Health problems related to tobacco use include cancers, lung disease, and heart disease. Over the past decade the

Cigarette/Tobacco Use Questions: (1) Have you smoked at least 100 cigarettes in your entire life? If Yes, (2) Do you now smoke cigarettes every day, some days, or not at all? percentage of current adult smokers has decreased; however, there are other means of smoking (e-cigarettes, vapes, etc.) that have become popular.

According to 2018 BRFSS data results, the group with the highest rate of current smokers is black males at 25.7 percent followed by white males at 22.2 percent and white females at 20.7 percent. The group with the lowest percentage of current smokers is black females at 12.9 percent (Figure 53).

Overall, the rate of current smoking in Mississippi is 20.5 percent. The Healthy People 2020 target objective is 12 percent. There are fluctuations in rates in current smoking by age group, with males between ages 25-34 having the highest rate at 30.4 percent (Figure 54). Among both male and female college graduates, the rates of current smoking are lower than other education levels at 8.3 and 8.5 percent respectively (Figure 55). Interestingly, both males and females with annual household incomes of $\$ 35,000$ or more had the lowest rates of current smoking (Figure 56). The rates were highest among those with annual household incomes of less than $\$ 15,000$, which is also evidenced in national smoking trends (US Department of Health and Human Services, 2014).

## Alcohol Consumption (Binge Drinking)

Extensive alcohol use has been linked to a substantial proportion of injuries and deaths from motor vehicle crashes, falls, fires and drowning. It also is a factor in homicide, suicide, marital violence and child abuse and has been associated with high risk sexual behavior.

> Alcohol Consumption Question:
> Considering all types of alcoholic beverages, how many times during the past 30 days did you have [ $X=5$ for men, $X=4$ for women] or more drinks on an occasion?

Persons who drink even relatively small amounts of alcoholic beverages may contribute to alcohol-related death and injury in occupational incidents especially if they drink before operating a vehicle. In 2016 alcohol use was associated 18.6 percent of all motor vehicle crash fatalities, according to the U. S. National Highway Traffic Safety Administration (2017).

Binge drinking in adults may be defined as those who are 18 years or older who have five or more drinks in one occasion for males and females who have four or more drinks on one occasion. According to 2018 BRFSS data, males have the highest rates of binge drinking compared to females (Figure 57). In addition, males 25 to 44 years of age report the highest rate ( 32.9 percent) of binge drinking (Figure 58).

As indicated in Figure 59, males with less than a high school diploma had the highest rate of binge drinking at 20.7 percent. However, females with annual household incomes of $\$ 75,000$ or more had the highest rate ( 10.5 percent) of binge drinking compared to females in lower income groups; and males with annual household incomes between $\$ 50,000$ and $\$ 74,999$ (23.2 percent) had the highest rate compared to males in other income groups (Figure 60.)

## IMMUNIZATION (FLU VACCINE)

Influenza and pneumonia conjointly were the eighth leading cause of death in Mississippi in 2017. During that year, 784 people died from these two conditions. The Healthy People 2020 goal for influenza vaccinations is to reach 90 percent of the non- institutionalized people age 65 and older having been vaccinated in the preceding twelve months. The influenza

## Flu Shot Question:

 During the past 12 months, have you had either a flu shot or a flu vaccine that was sprayed in your nose?Note: Analyses include men \& women age 65 and older vaccine can prevent the disease and several complications that are associated with the flu. In the elderly population, the vaccine is less effective in disease prevention; however, it does reduce the severity and incidence of complications and death.

Based on 2018 BRFSS survey results, 60 percent of the respondents age 65 and older reported they had received the influenza vaccine in the past 12 months. The proportion vaccinated in this age group reflected a marked difference according to race: 63.6 percent of whites reported having been vaccinated compared to only 51.3 percent for blacks (Figure 61). Interestingly, female respondents with less than a high school diploma had the highest rate ( 67.7 percent) compared to females in other education groups, whereas, males who are college graduates had the highest rate at 69.5 percent compared to males who were not college graduates (Figure 62). Figure 63 indicates that female respondents with annual household incomes between $\$ 25,000$ and $\$ 34,999$ had the highest rate of flu vaccinations at 66.4 percent compared to the other income groups.

## IMMUNIZATION (PNEUMONIA VACCINE)

According to the World Health Organization or WHO (2019), pneumonia is a form of acute respiratory infection that affects the lungs. This condition may and can cause mild to severe illness in people of all ages, with symptoms including, but not limited to, cough, fever, and

Pneumonia Shot Question: Have you ever had a pneumonia shot also known as a pneumococcal vaccine?

Note: Analyses include men \& women age 65 and older difficulty breathing. National data from 2017 to 2018 indicates that the age-adjusted death rates for influenza and pneumonia increased by 4.2\% (Xu, Murphy, Kochanek, \& Arias, 2020).

The 2018 BRFSS results revealed that 68.7 percent of respondents aged 65 and older said they had ever received a pneumonia vaccination. As indicated in Figure 64, the majority of white female respondents age 65 and older reported ever having a pneumonia shot at 75.8 percent. Similar to influenza vaccinations rates for those 65 years of age and older, there was a marked difference with respect to race for pneumonia vaccinations: 73.2 percent for whites but only 57.7 percent for blacks. Interestingly though, the rate for whites was 77.4 percent in 2017 and 56.3 percent for blacks that same year.

As indicated in Figure 65, respondents with some post-high school education had the highest rate ( 73.7 percent) among those age 65 and older who had ever received a pneumonia shot/vaccine (Figure 65). There were variations among both male and female respondents' annual household income levels; however, males with annual household income levels from $\$ 50,000$ to $\$ 74,999$ had the highest rate ( 80.2 percent) for ever having a pneumonia (Figure 66) shot.

## HIV/AIDS (TESTING)

The CDC (2019) estimates that nearly 1.1 million people aged 13 and older had Human Immunodeficiency Virus (HIV) infection at the end of 2016 in the U.S. This number includes an

HIV/AIDS Testing Question:
Have you ever been tested for H.I.V.? Do not count tests you may have had as part of a blood donation. Include testing fluid from your mouth. estimated 162,500 (14\%) whose infections had not been diagnosed. Despite increases in the total number of people in the U.S. living with HIV infection in recent years (due to better testing and treatment options), the annual number of new HIV infections declined by five percent from 2011 to 2015 .

In 2017, 112 people died as a result of HIV in Mississippi. In the U.S., 507,351 people have died with the disease since 1987 when it began to be listed as a cause of death on death certificates. Even though the two main causes of HIV infections in the U.S. are sexual intercourse and intravenous blood use, the condition may potentially also be caused by the transferal of blood and breast milk.

The 2018 BRFSS data revealed that 41 percent of respondents reported that they had never been tested for HIV. More black respondents had been tested at 56.5 percent compared to whites at 30.1 percent (Figure 67); however, the rate of HIV testing for other races (Non-Hispanic) was higher than both blacks and whites at 66.5 percent. Figure 68 revealed that females between the ages of $35-44$ had the highest HIV testing rate ( 64.6 percent) among females, and males between the ages 25-34 had the highest HIV testing rate (54.2) compared to males in other age groups. Respondents who have some post high school education and/or are college graduates had the highest HIV testing rates (Figure 69). Interestingly, both males ( 50.5 percent) and females ( 55.4 percent) with annual household incomes less than $\$ 15,000$ had the highest rates of HIV testing (Figure 70).

## Seat Belt Usage

The Centers for Disease Control and Prevention (2018) reports total of 23,714 drivers and passengers in passenger vehicles died in motor vehicle crashes in 2016 and more than half of teenagers and adults

Seat Belt Usage Questions:
(1) How often do you use seat belts when you drive or ride in a car? (2) Would you say always, nearly always, sometimes, seldom or never?

Analyses based on "always wear seat belts" aged 20-44 years who died were not buckled up when the crash occurred. According to the National Highway Traffic Safety Administration (NHTSA, 2018) in the United States during 2018, 36,560 lives were lost on roads in 2018.

Additional highway safety statistics indicate that 1 out of 2 people killed in motor vehicle crashes in Mississippi are not buckled up (Mississippi Department of Transportation, n.d.). Because using seatbelts have been proven to save lives, it is recommended throughout the nation that all persons in a vehicle buckle their seatbelts prior to moving. Ejection from the vehicle is one of the most injurious events that can happen to a person in a crash. Seat belts can be effective in preventing total ejections.

The 2018 BRFSS data in Mississippi revealed that 82.9 percent of adults aged 18 and over always wear a seat belt when they either drive or ride in a car. Overall and within each age group, females report that they always wear seat belts more often than men (Figures 71 and 72). Figure 73 indicates that those who are college graduates had slightly higher seat belt usage rates than those with less education. Females with annual household incomes of $\$ 75,000$ or more had the highest rate of seat belt usage at 89.8 percent compared to other female income groups; whereas, males with less than $\$ 15,000$ had the highest rate of usage ( 80.4 percent) compared to males with annual household incomes of more than $\$ 15,000$ (Figure 74).

## ORAL HEALTH

Oral health is just as important as mental and physical health. More and more health conditions are being linked to oral health as a result of bacteria and inflammation that may occur in the mouth. Gum disease can allow bacteria to enter the bloodstream and contribute to a wide range of chronic health

## Oral Health Question:

Including all types of dentists, such as orthodontists, oral surgeons, and all other dental specialists, as well as dental hygienists, how long has it been since you last visited a dentist or a dental clinic for any reason?

Analyses based on those who visited an oral health provider within the past year
problems including, but not limited, to preterm birth, poorly controlled diabetes and cardiovascular disease.

The CDC (2019) suggests that some of the most common diseases that impact oral health include tooth decay (cavities), gum (periodontal) disease, and oral cancer. Also, oral conditions are frequently considered separate from other chronic conditions, however, these are actually inter-related. Seeing an oral health provider can limit the risk for these cancers and other interrelated chronic health conditions.

When respondents were asked how long it had been since they visited a dentist or dental clinic (for any reason), the 2018 BRFSS data revealed that over half, 54.1 percent, had visited one within the past year. Figure 75 indicates that white females had the highest rate of oral health visits within one year at 57.3 percent. Both males and females ages 18-24 had the highest rates [ 63.7 percent females; 62.7 percent males] of oral health visits within one year compared to the other age groups (Figure 76). Data also revealed that vast differences exists by education. The oral health visit rate is doubled from those who have less than a high school diploma compared to those who are college graduates (Figure 77). Similarly, those with higher annual household incomes had highest rates of oral health visits within one year compared to other income groups (Figure 78).

## MS BRFSS DATA BRIEFS

## State Module Questions

## Pre-Diabetes (TESTING)

It is important for everyone to be cognizant of his/her blood sugar levels. According to CDC (2019), prediabetes is a serious health condition where blood sugar levels are higher than normal, but not high enough yet to be diagnosed as type 2 diabetes. Approximately 84 million American adults-more than 1 out of 3-have prediabetes. Of those with prediabetes, $90 \%$ don't know they

## Prediabetes

 Testing Question: Have you had a test for high blood sugar or diabetes within the past three years? have it. This condition can potentially lead to and/or put someone at risk for developing Type II Diabetes. In addition, pre-diabetes may increase risks for other chronic conditions such as heart disease and stroke.In 2017, in Mississippi, Diabetes Mellitus was the seventh leading cause of death with 1,163 people dying from the condition. This disease accounted for $3.6 \%$ of all deaths in the state that year. Because blood sugar levels are a determining factor for this condition, it is important that adults are periodically tested, especially for those having pre-existing risk factors for diabetes.

Among adults that reported that they had a test for high blood sugar or diabetes within the past three years, 53.6 percent responded "yes." Figure 1 indicates that black females had the highest rates for pre-diabetes testing within three years at 58.5 percent. Figure 2 reveals that as age increases, so do the rates for both males and females who had pre-diabetes testing within three years. Overall, similar to other health conditions, as education and annual household income levels increase so do the rates for pre-diabetes testing (Figures 3 and 4).

## Pre-Diabetes (Health Professional Diagnosis)

Having a medical professional tell someone they have diabetes may be life altering. The person may have to make decisions to change his/her diet, exercise, or other alteration that may not have been a part of their current routine. However, with modest weight loss and

Prediabetes
Diagnosis Question: Have you ever been told by a doctor or other health professional that you have pre-diabetes or borderline diabetes?
moderate physical activity, a person can delay or prevent type 2 diabetes.

During pregnancy, this could be a difficult diagnosis in that the mother-tobe will have to make changes to ensure that she does not put her pregnancy [and baby] at risk. Also known as gestational diabetes, this particular condition affects only pregnant women. This condition may affect pregnant women who have never been diagnosed with diabetes.

According to the 2018 BRFSS, 8.3 percent of adults reported ever being told by a health professional that they have pre-diabetes or borderline diabetes. During pregnancy, 0.9 percent of women reported that they had been told they have pre-diabetes or borderline diabetes. Figure 5 indicates that black females had the highest rate at 11 percent of ever been told they have pre-diabetes or borderline diabetes. Figure 6 indicates that as people aged, so did the rate of ever being told that they have pre-diabetes or borderline diabetes. Respondents with less than a high school diploma reported the highest rate of ever being told they had pre-diabetes or borderline diabetes at 9.8 percent. In both males and females, those with annual household incomes between $\$ 25,000$ and $\$ 34,999$ had the highest rate of ever being told they had pre-diabetes or borderline diabetes at 11.8 and 14.9 percent respectively.

## DIABETICS (CURRENTLY TAKING INSULIN)

Insulin is sometimes needed for diabetics who aren't naturally able to control their blood-sugar levels. In particular, Type II diabetes develop because the cells in the muscles, liver, and fat do not use insulin properly. As a result, the amount of sugar in the blood increases, while the

Diabetics<br>(Currently<br>Taking Insulin) Question:<br>Are you now taking insulin? cells are starved of energy. Over time, high blood sugar damages nerves and blood vessels, leading to complications such as heart disease, stroke, blindness, kidney disease, nerve problems, gum infections, and amputation.

Diabetics use insulin to help control their blood-sugar levels. This is part of treatment management for those who need this drug to help maintain their overall health.

As revealed in the 2018 BRFSS results, 33.1 percent of those with diabetes (ages 35 and older) are currently take insulin. Figure 9 indicates that the rates for blacks currently taking insulin are higher at 37.4 percent compared to whites at 30.7 percent. Both female and male respondents ages $45-54$ had the highest rates of currently taking insulin at 40.7 and 35.2 percent respectively (Figure 10). Overall, those ages 35 and older with less than a high school diploma had the highest rate of currently taking insulin at 39.8 percent (Figure 11). As indicated in Figure 12, respondents [age 35 and older] with annual household incomes of less than $\$ 15,000$ had the highest rate of currently taking insulin at 37.4 percent.

## DIABETICS (RETINOPATHY)

Retinopathy is a condition that may affect the retina of the eye in people who are diabetic. This condition may also be called diabetic retinopathy.

Diabetics (Retinopathy): Has a doctor ever told you that diabetes has affected your eyes or that you had retinopathy?

According to the CDC (2018), from 2010 to 2050, the number of Americans with diabetic retinopathy is expected to nearly double, from 7.7 million to 14.6 million. Adults over age 40 years with diabetes and those who have other comorbid conditions may be at an increased risk for diabetic retinopathy.

2018 BRFSS data reveal that 19.2 percent of adults age 35 and older had ever been told by a doctor that diabetes has affected their eyes or had retinopathy. Of this rate, 16.9 percent are males and 21.1 percent are females. In addition, 18.8 percent are white and 21.1 percent are black.

Figure 13 indicates that black and white females had the highest rates of being told they ever had retinopathy at 21.2 percent and 21.9 percent respectively. Among males and females ages 45 and older, those between ages 45-55 had the highest rates of ever being told they have retinopathy (Figure 14).

Figure 15 indicates that those 35 and older with some post high school education had the highest rate of ever being told they have retinopathy at 23.5 percent. As indicated in Figure 16, respondents with annual household incomes between $\$ 15,000$ and $\$ 24,999$ had the highest rate at 22.4 percent and respondents with incomes of $\$ 75,000$ or more having the lowest prevalence at 16.3 percent.

## DIABETICS (MANAGEMENT CLASS)

Controlling diabetes is of the utmost consideration among those who are diabetic. People who are diabetic have several avenues that they can take to receive assistance in self-management of their diabetes. Some of these include hospitals, clinics, web-based resources,

Diabetics<br>(Management Class):<br>Have you ever taken a course or class in how to manage your diabetes yourself?

According to the American Diabetes Association (ADA, 2017), diabetes selfmanagement education and support (DSMES) is a critical element of care for people with diabetes. This type of support is an ongoing process of facilitating the knowledge, skills, and ability necessary for diabetes self-care, as well as activities that assist a person in implementing and sustaining the behaviors needed to manage his or her condition on an ongoing basis, beyond or outside of formal selfmanagement training.

According to 2018 BRFSS data, 40.1 percent of respondents aged 35 and older said that they had ever taken a course or class in how to manage their diabetes. Further, black females had the highest rate of ever having a class/course in diabetes management at 50.4 percent (Figure 17).

Figure 18 indicates that respondents ages 45-54 had the highest rates of ever having a class/course in diabetes management. Accordance to education levels, respondents who are college graduates had the highest rates of ever having a class/course in diabetes management (Figure 19). Similarly, Figure 20 indicates that respondents over 35 with annual household income levels greater than $\$ 35,000$ also had the highest rates compared to lower income levels.

Figure 18. Ever Had Class/Course in Diabetes Mgt.

## E-CIGARETTES/VAPING (EVER USED)

E-cigarettes (a.k.a. electronic cigarettes) have become more and more popular in recent years. Research from the CDC (2020) suggests that E-cigarettes produce an aerosol by heating a liquid that

> E-cigarettes/Vaping
> Question (Ever Used):
> Have you ever used an ecigarette or other electronic vaping product, even just one time, in your entire life? usually contains nicotine-the addictive drug in regular cigarettes, cigars, and other tobacco products-flavorings, and/or other chemicals that help to make the aerosol. When users inhale this aerosol into their lungs, there can be adverse health effects. Bystanders can also breathe in this aerosol when the user exhales into the air.

In Mississippi, according to 2018 BRFSS data, 25 percent of respondents (male and female) said that they had ever used e-cigarettes or electronic vaping at least once in their lifetime. Of this percentage, 28 percent are white, 19.1 percent are black, and 34.5 percent are of another Non-Hispanic race.

As indicated in Figure 21, the highest rates were among white males ( 31.5 percent) and white females ( 24.9 percent) for having ever used an e-cigarette or electronic vaping product. Figure 22 indicates that as age increases, the rate of adults who ever used an e-cigarette or vaping product decreases. The highest age group for having used are both males ( 49.8 percent) and females ( 39.1 percent) between the ages of 18-24. College graduates had the lowest usage rate at 17.4 percent (Figure 23).

In regard to income (Figure 24), both male and female respondents with annual household incomes of $\$ 75,000$ or more had the lowest rates of ever having used e-cigarettes or an electronic vaping product.

## E-CIGARETTES/VAPING (CURRENT USE)

Vaping has become a public health crisis across the U.S. When vaping originated, it was coined as not being as harmful as smoking cigarettes and/or using other tobacco products. However, over the past

E-cigarettes/Vaping Question (Current Use): Do you now use ecigarettes or other electronic vaping products every day,
some days, or not at all? several years, researchers have identified several harmful effects, including death, of e-cigarettes and vaping.

National 2017 BRFSS data revealed that the crude prevalence for adults who never used e-cigarettes was 79.3 percent, which suggests that roughly 20.7 percent either currently, sometimes, and formerly used e-cigarettes.

Mississippi 2018 BRFSS data reveal that 9.2 percent of respondents said that they use e-cigarettes or other electronic vaping products every day and 13.3 percent said they use them some days.

Figure 25 indicates that a combined total of 26 percent of white males responded that they either use e-cigarettes or other electronic vaping products every day or some days, which signifies the highest group currently using. Black females had the lowest rate of current use at 12.6 percent.

Data by age group revealed that male and female respondents between ages 18-44 had the highest rates of using e-cigarettes or electronic vaping products every day or some days (Figure 26). Respondents with less than a high school diploma had the lowest rate at 14.9 percent (Figure 27). Data results also revealed that adults with annual household income levels between \$50,000 and \$74,999 had the highest usage rates at 28.1 percent.

Figure 27. Currently Use E-cigs or Vaping Product

## AdULT HUMAN PAPILLOMAVIRUS (HPV) VACCINATION

The Human Papillomavirus (H.P.V.) is a common condition that can cause cancer in both men and women if left untreated. According to the CDC (2019), nearly 80 million of Americans are currently infected with some type of H.P.V. and about 14 million, including teens,

HPV Vaccination Question:
Have you ever had an H.P.V. vaccination? become infected each year.

The H.P.V. vaccination helps prevent infections that lead to many H.P.V.related cancers which include, but are not limited to cervical, vaginal, anal, and throat cancer. The CDC (2019) estimates that H.P.V. causes nearly 35,000 cases of cancer in men and women each year.

Data from the 2018 Mississippi BRFSS revealed that 12.3 percent of males and females ages 18-54 reported that they ever had an H.P.V. vaccination. Figure 29 indicates that both white and black females are almost equal for ever having an H.P.V. vaccination at 19.6 and 19.3 percent respectively. More black males received the vaccination at 6.6 percent compared to 3.9 percent white males. Great disparities exist among women and men ages 18-54 who ever received an H.P.V. vaccination; however, females between the ages of 18-24 had the highest rate at 41 percent (Figure 30). As indicated in Figure 31, females across each education level had higher H.P.V. vaccination rates than males. Similarly, females across each income level also had higher H.P.V. vaccination rates compared to males having the same annual household income levels (Figure 32).

## APPENDIX A: CORE QUESTIONS

| TABLE 1. Health Status <br> Denominator excludes respondents with do not know/refused/missing responses |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

## APPENDIX C

## Summary of Terms and Risk Factors

## Alcohol Consumption

Binge Drinking Risk Factor - Respondents who report that they have had at least five drinks on one or more occasion during the past thirty days.

Heavy Drinking Risk Factor - Male respondents who report having more than fourteen drinks per week and female respondents who report having more than seven drinks per week.

## Arthritis

Arthritis Awareness - Respondents who have been told by a doctor or other health professional that they have some form of arthritis, rheumatoid arthritis, gout, lupus, or fibromyalgia.

Limited Activity - Respondents who report that their usual activities are limited because of joint pain caused by arthritis.

Limited Work - Respondents whose joint symptoms because of arthritis affect whether they can work or affects the amount and type of work they do.

## Asthma

Asthma Awareness - Respondents who report being told they have asthma by a doctor, nurse or other health professional.

Current Asthma - Respondents who report that being told they have asthma by a doctor, nurse or other health professional and who still suffer from the condition.

## Cancer Screenings

Mammograms - Respondents who reported ever having a mammogram.
Cervical- Respondents who reported ever having a pap test and/or how long its been since the last pap test.

Prostate - Respondents who reported ever having a prostate-specific antigen test (P.S.A.).

## Cardiovascular Disease

Heart Attack - Respondents who report that they have ever been diagnosed with a heart attack.
Stroke - Respondents who report that they have ever been diagnosed with a stroke.
Coronary Heart Disease - Respondents who have ever been diagnosed with angina or coronary heart disease.

## Cigarette Smoking

Cigarette Smoker - Respondents who have ever smoked 100 cigarettes in their lifetime and report currently smoking every day or some days. This relates to Healthy People 2020 Objective 27 - Target $\leq 12 \%$.

E-Cigarette Smoker - Respondents who have ever used an e-cigarette or other electronic vaping product.

## Diabetes

Diabetes Awareness - Respondents who report they have ever been told by a doctor that they have diabetes. Female respondents diagnosed with diabetes only during pregnancy are not included.

At Risk for Diabetes (Pre-Diabetes) - Respondents age 18 to 44 who are obese and report no exercise in the past 30 days, or respondents age 45 to 64 who are either obese or report no exercise in the past 30 days, or respondents age 65 and older who are obese.

## Disability

Limited Activity - Respondents who report that their activity is limited in any way because of physical, mental or emotional problems.

Special Equipment Requirements - Respondents who report having health problems that require the use of special equipment such as a cane, wheelchair, special bed or special telephone.

## Exercise

Exercise in Last 30 Days - Respondents who report that, excluding their regular job, in the past 30 days they participated in any physical activity or exercise such as running, walking, calisthenics, golf, or gardening.

## Health Insurance

Health Care Coverage - Respondents who report they have no health care coverage, including health insurance, Health Maintenance Organizations, or Medicare.

Unable to See a Doctor - Respondents who report they needed to see a doctor within the past 12 months but were unable because of the cost.

## Health Status

Self-Reported Health Status - Respondents who report that their general health status is fair or poor.
Healthy Days
Physical Health - Respondents who report more than seven days during the past month when their physical health was not good.

Mental Health - Respondents who report more than seven days during the past month when their mental health was not good.

Activities Limited - Respondents who report more than seven days during the past month when they could not perform their normal activities because of poor physical or mental health.

## HIV/AIDS

Ever Tested for HIV - Respondents age 18 to 64 who report that they have ever been tested for HIV, excluding tests done as part of a blood donation.

High Risk Behavior - Respondents age 18 to 64 who report that they have used intravenous drugs, have been treated for a sexually transmitted or venereal disease, have given or received drugs or money in exchange for sexual favors, or have had anal intercourse without a condom during the past year.

## Hypertension

Hypertension Awareness - Respondents who have ever been told they have high blood pressure by a doctor, nurse or other health professional.

Taking Blood Pressure Medicine - Respondents who have been told they have high blood pressure by a doctor, nurse or other health professional and who are taking medication to control it.

## Immunization

Flu Shots - Respondents who report receiving a flu shot or the flu spray vaccine within the last twelve months.

Pneumonia Shots - Respondents who report ever receiving a vaccination for pneumonia.

## Mental Health

Depression Awareness - Respondents who report they have been diagnosed by a health professional with depression.

## Physical Activity

Highly Active - Respondents who report doing enough physical activity to meet the 300-minute per week (or vigorous equivalent) aerobic recommendation.

Active - Respondents who report doing 150-300 minutes per week (or vigorous equivalent) of physical activity.

Insufficiently Active - Respondents who report doing insufficient physical activity (11-149 minutes per week).

Inactive - Respondents who report doing no physical activity.

## Seat Belts Usage

Respondents who report they always, or nearly always wear seat belts.

## Weight Based on Body Mass Index (BMI)

Body Mass Index (BMI) - Weight in kilograms divided by height in meters squared $(\mathrm{kg} / \mathrm{m} 2)$.

Healthy Weight - Respondents with a BMI $18.5 \leq$ BMI $\leq 24.9$.
Healthy People 2020 Objective 19.1 - Target $\geq 60 \%$.
Overweight - Respondents with a BMI $25.0 \leq \mathrm{BMI} \leq 29.9$.
Obese - Respondents with a BMI $\geq 30.0$. This measures Healthy People 2020
Objective 19.2 - Target $\leq 15 \%$.
